FirstExercise

We will create a simple API to manage profiles.

1. install Laravel on your machine by following the instruction at the following link: https://laravel.com/framework/docs/installation#installing-php
2. create a new laravel project:
   `laravel new project_name`
3. Copy the attached files into your project (same paths):

   ```
   app/Models/Profile.php
   app/Http/Controllers/ProfileController.php
   routes/api.php
   storage/app/profiles.json
   ```

   Then run `php artisan serve` in the terminal or CMD, make sure you are inside the project's directory.
4. Open postman or any API testing app you wish and test the `http://localhost:8000/api/profiles/` endpoint as a GET request.
5. follow the laravel code of the endpoint through the files to learn how it's been created:
   `api.php --> ProfileController.php --> Profile.php --> ProfileController.php`

---

6. Do the same for the `/api/profiles` as a POST request; pass the following json object as the body of the request:

   `{ "first_name":"schrodinger", "last_name": "cat", "is_account_verified":false, "followers":0 }`
   you should get something like this:

---

7. Fix the bug of the delete route in `api.php`, and test the endpoint in postman by deleting the profile you created in the the previous step, then make sure the profile was deleted by requesting the `http://localhost:8000/api/profiles/` endpoint as a GET request.

8. Try this route `Route::get('/profiles/{id}', [ProfileController::class, 'show']);` find the bug (missing implementation) and fix it!.

---

9. Lastly you will create an API endpoint to update an already existing profile by passing its `id` as a path parameter; note that the the endpoint should return an error message if it couldn't find the profile that the user is trying to delete.
